sonthern Texas, Louisiana and Florica is only from 17.6 to 18.4 mm . This larger animal is Dasypterus intermedius (II. Allen), originally deseribed from Matamoras, Tamanlipas. While it is not possible, in the absence of a hetter series of skins than that now available, to find any appreciable differences between the V'ucatan and (hiapas specimens and true intermedius, it is evident that the form ocemring in Louisiana and Florida ( $D$. floridanus Milker) is sutliciently characterized liy its shorter forearm and third finger to be regarded as distinct.

## THE VOLC.INO RABBIT OF MOUNT IZTACCIHUATL.*

In the catalng of the object- exhibited by the Mexican "Comision Geográfien-Exploradora'" at the Columbian Exposition in Chicago + Professor Augutin Diaz figures (pl. ti2) a rablit of the gems Romerolagns. under the name "Conejo del Volcán (Lepus diazi Ferrari-Pérez, sp. now )." This plate is not mentioned ly Merriam in the original deseription of Romerolayns nelsoni* from Mlt. Popocatepetl, on ly Nelson in his monograph of the Rahbits of North America, $\oint$ though it is alluded to by an anonymons editorial writer in Natural seience for March, 18:17.\|

The validity of the specific name diazi is monestionalble under the
 Aceording to the samm Code the anthority for the name is Diaz, mot Ferrari-P'érez, since Lepus diazi remaned in Ms. until the publication of the catalng hy biaz, and no statement is anywhere makle that "some other person is responsil, fer for publication of sail name amb its indication [ $=$ illustration]" (Art. :21, and Opinion 4).

Nomenclatorily the cave presents no difticulties, but zoolngically it has hitherto been obsemed by the meertanty as to whether the "Voleano Rabbit" was identical with Romerolagus nolsoni. This doubt has now been removed by the kindness of Professor Ferrari-Pérez, through which 1 have been enabled to examine the type and a second specimen of Romerolagus diazi. both were taken in Puehla, on the eastern shope of It. Iztarcihuatl, a region about fifteen miles from the type-locality of Romerolagus nelsomi.

As compared with fone skins of Romerolagns nelsoni the two specimens of R. diazi (both marked female, the type taken in Mareh, 1s.5.) show slighty less black in the grizale of dorsal surface and slightly more gray on cheeks, characters probably due to the fiading usual in mounted spec-

imens. The skull of the type (that of the other specimen is miswing) lack: the mandible and the entire hasal part of braincase, though the remaining portion is in fair eondition. It has certain peenliarities mot Shared hy any of the fise sknlls of $l$. nelsoni: the postorlital procesese are bromer amb heavier, the patate is more arched between toothrows, and the doreal protile of branease is less bent downard posteriorly. These cranial characters are, however, quite within the range of normal Variation in members of the family. I consequently have no hesitation in regarding the later name nelsoni as a synonym of diazi. Mr. E. Wr. Nelson, who examined the specimens with me, is of the same opinion.*

Weasurements of the type secimens those of R. "nelsoni" in parentheris): hind foot, 48.6 ( $5: 3$ ) ; ear from crown, 38.6 (37); greatest length of skull, ( $60.4(60.6)$; zygomatic breadth, 2! $+(30.4)$; brealth of brain(ase e, e2. ( 6 (2:3.t) ; powtorbital constriction, 10.0 (9.s); interorbital constriction ! $1.8(10.0)$; nasal, $24.4+(24.8)$; greatest breadth of both masals together, ! ! S (10.0); diastema, 16.0 ( 15.8 ); length of palate (lateral), 7.t (7.i') ; width of palate hetween anterior premolars, 8.0 ( $7 .(6)$; width of palate between posterior molars, 10.4 (10.6); depth at midule of palate, $1: 3$ ( 14.0 ); maxillary towthrow (alveoli), 11.6 (12.0).

Nore.-Four specimens (Nos. 174.31-4) collected at Textlananguila on Momont Iataccihatl, above Amecameca, and presented to the U. S. National Mnseun by Irofesor Ferrari-Pérez, arrived in Washington after this article was in type. They entirely confirm the identity of Romerolagus diazi amd R. "nelsomi".

[^0]
[^0]:    *In view of Mr. Nelson's personal acquaintance with the region where the two tyms were collected I requested him to giveme a brief account of the geography. This he hat kimbly done as follows: "The total area ocupied by Romerolagus appears to be limited to the middle slopes of the volamos Popocatepetl and Iztaceihuatl. The boundary line between the states of Mexicoand Puebla runs along the crests of these mountails in a northerly and southerly course, thus placing the western slopes in Mexico and the eastern ones in Puebla. These mountains are joined by a broad ridge about 12.000 feet high, at each end of which rise the high peaks. The middle slopes, where Romerolagus lives, are continuous arombloth mountains and lie in an area 20 miles long, in a north and south direction, and ten miles broad, from east to west. Romprolugus lives permanentis only where it bas the shelter of the coarse saccaton grass and the areas occupied by this plant are broken by hot slopes on which it can not maintain itself. These breaks are not wide and can be readily crossed by small mammals. The extremely limited a rea which Romerolagus occupies, and the absolute identity of climatic and other physical conditions within it, appear to prechude the possibility of the existence of more than one local form."
